CONTENTS

ABSTRACT

Carry over effects of a program to suppress a western spruce budworm, Choristoneura occidentalis Free., outbreak were achieved for a second year on the Santa Fe National Forest and Jemez Pueblo Indian Reservation, New Mexico. There was an average of 14.9 larvae per 100 buds on Douglas-fir in the spray area (37,450 acres) prior to treatment in 1977, about one larva per 100 buds remaining 14 days following treatment, and less than one larva per 100 buds were present in 1978. The average larval density per 100 buds of Douglas-fir in a comparable untreated check area (37,398 acres) was 12.4 for 1977 pre-spray sample, 6.9 for 1977 post-spray sample, and 8.7 for 1978 pre-spray sample. In 1978, the larval density in the untreated check area was nine times greater than in the treatment area. An average of 0.4 egg masses per meter square of foliage was recorded in the treatment area in 1978, compared with 10.1 density in the unsprayed area. Overall, egg mass density data indicate that larval densities will remain at about the same level in the unsprayed area in 1979 as found in 1978, but larval densities should decrease further in the treatment area. Defoliation in the treatment area in 1977 was about half of that recorded in the untreated check area and about one-tenth in 1978.

The only measured adverse environmental effect of the treatment was a reduction of some aquatic insects in one small stream that had been partially sprayed. Three families of aquatic insects had not recovered 1 year following treatment: Plecoptera-Chloroperlidae and Nemouridae; and Diptera-Stratiomyidae. Overall, the insect biomass was comparable for 1977 and 1978. There were no significant reductions in aquatic insects in two other creeks sampled in the treatment area that were not directly sprayed.

No adverse effects of treatment could be identified for birds, small mammals, reptiles, and non-target insects.

Tentative results of sampling of insect parasites of the budworm are presented.

Evaluation of effectiveness of suppressing the budworm outbreak will continue through 1979. Tree damage assessment and monitoring of aquatic insects in the three streams in the treatment area will be done.

I. INTRODUCTION

In 1977, Sevin ^{R} -4-oil was aerially applied on 37,450 acres of forested land to suppress a western spruce budworm, Choristoneura occidentalis Free., outbreak. The project, entitled Western Spruce Budworm Suppression and Evaluation Project, was done in an isolated mountain range on the Santa Fe National Forest and Jemez Indian Pueblo, New Mexico, where the possibility for reinfestation from nearby infestations was minimal. The objectives were to: 1) In 1977, suppress the budworm population to an acceptable level (criteria established to show success were reducing the budworm larval density by an average of 90 percent and obtaining an egg mass density of 1.5 new egg masses per square meter or about one egg mass per thousand square inches of foliage); 2) For 2 additional years, evaluate prolonged effectiveness of suppressing the budworm outbreak by gathering larval and egg mass data in the treatment area and a comparable untreated check area (37,398 acres); and 3) Evaluate annual defoliation and cumulative tree growth loss, mortality, and top-kill in the treatment and untreated areas.

The application phase of the project was successfully completed in 1977 (Parker et al. 1978).[1/] The 1976-7 budworm generation was reduced by an average of 93.1 percent compared with a 44.5 percent reduction in the untreated area. The adjusted budworm mortality, using Abbott's formula, was 87.5 percent. The average density of new egg masses was 1.6 per square meter (1.0 new egg masses per 1,000 square inches) in the treated area, and 11.2 per square meter (7.2 per 1,000 square inches) in the untreated area. Even though an average of 84.1 percent of the budworm larvae were in the latter instars (fifth and sixth) and 0.3 percent were pupae at the time of treatment, defoliation in the treatment area was considerably less than in the untreated area: treatment area-26.5 percent for Douglas-fir and 37.1 percent for white fir; untreated area-40.8 percent for Douglas-fir and 61.3 percent for white fir.

The purpose of this report is to document data collected in 1978. Also, raw data for larval and egg mass densities and defoliation in 1977 and 1978 are presented in the Appendix.

II. METHODS

A. Entomological Phases

1. Sampling Locations

The treated and untreated areas were divided into six subunits in 1977 (Figs. 1 and 2). In each subunit, 25 permanent plots (3-tree cluster) were established, as uniformly as possible, throughout each subunit along roads and trails. Each plot was assigned a unique number.[2/] Data will be collected on these permanent plots until at least 1979.

2. Timing of Larval Sampling

For between-year-comparison of late-instar larval densities, sampling had to be done at about the same developmental point in the yearly cycle of the budworm. As a result, budworm larval development had to be closely monitored.

In 1978, development sampling was initiated in late May on all development clusters. Data were obtained from five 2-tree clusters located throughout the range of exposure and elevational differences in each subunit. Trees sampled for budworm development were not the same as those used to estimate late-instar larval densities, but clusters were at the same location.

Development sampling was started in late May and continued intermittently until buds began to swell. Then, development sampling was done every other day until 90 percent of current bud caps dropped, or 90 percent of the larvae were in the third and fourth instars. At this time, daily sampling was done until at least 20 percent of the larvae were in the fifth and sixth instars.

3. Evaluating Second-Year Project Effectiveness

The lasting effectiveness of insecticide treatment was determined by (1) measuring budworm larval and egg mass densities in 1978, and (2) comparing them with similar data collected in 1977.

2/ Identifying cluster numbers and their locations are shown in Figures 38 to 53 in Progress Rep. No. 1, Ibid.

a. Sampling Design for Larvae

Larval sampling began when 20 percent of the larvae were in the fifth and sixth instars. Larval density data were obtained on up to 25 plots per subunit. In some subunits, fewer than 25 plots were sampled. Six plots were destroyed by fire and logging, and four were inaccessible due to road closures. Three trees were sampled per plot. Sample trees were codominant Douglas-fir, 30 to 50 feet in height, and relatively open-grown with full crowns. Sample branches were cut from opposite sides of the midcrown of trees with a pole pruner and attached collecting bag. Larval densities were expressed as larvae per 100 live buds to give equal weight to each branch sampled. Cluster means were computed by averaging the larval density on each sample branch per tree, and then averaging the 3-tree means.

b. Sampling Design for Egg Masses

In late July, two branches (70 cm in length) were cut from opposite sides of sample trees on permanent plots. The length and width of each branch was used to calculate foliated branch area.

Foliage from all branches were examined under ultraviolet light for egg masses. Needles bearing egg masses were classed as from current year's foliage, or a previous year, and kept separate in labeled pill boxes. New and old egg masses were separated under a stereomicroscope. All egg masses on current year's foliage were classed as new, and their characteristics formed the basis for aging those egg masses found on the previous year's foliage.

c. Analysis of Population Reduction

Estimates of two types of population density per plot were computed for each sampling period--year 1 and year 2. Larval densities were expressed as the number of late-instar larvae per 100 live buds. Egg mass density was expressed as number of new masses per square meter (1550 sq. in.) of foliage. Subunit and treatment level means and standard errors were computed as follows:

(1) Subscripts:

i = treatments	1 = spray	2=check
j = subunit	j = 1, 6	
k = cluster	k = 1, 25	
l = tree	l = 1, 3	
m = branch	m = 1, 4 for larval density	
	m = 1, 2 for egg density	

(2) Cluster Level:

Pre-spray population

$$pre_{ijk} = \frac{\sum_{l=1}^{3} \sum_{m=1}^{2} \frac{budworm_{ijklm}}{buds_{ijklm}} \quad (100)}{6}$$

Originally, there were 300 cluster level values for each variable (2 treatments X 6 subunits X 25 clusters = 300), but 290 values were used because 10 plots were lost.

(3) Subunit Level Calculations of Means and Standard Errors. Means and standard errors were calculated for each of the three variables at the subunit level. The formulas follow, using X_{ijk} as an example for one of the variables.

$$X_{ij} = \sum_{k=1}^{n} \frac{X_{ijk}}{n}$$

, where X_{ij} is the mean for the j^{th} subunit in the i^{th} treatment.

$$S.E.\ x_{ij} = \sqrt{\frac{\sum_{k=1}^{n} x_{ijk}^2 - \left(\sum_{j=1}^{n} X_{ijk} \right)^2 \Big/ n}{(n-1)}},$$

where S.E. x_{ij} is the standard error of the mean x_{ij}.

(4) Treatment Level Calculations of Means and Standard Errors. Assumptions made for each of the subunits are independent of each other and are self-weighting.

$$X_i = \sum_{j=1}^{6} X_{ij/6}$$ where X_i is the mean for the i^{th} treatment.

$$S.E.\ x_i = \sum_{j=1}^{6} S.E.\ x_{ij}^2$$

(5) Statistical Tests. Budworm densities were compared for the same year between the treated and untreated check populations, as well as comparing the densities between years for the same populations.

For populations with possibly different means, but a common variance, the general linear model was expressed by the following:

$X_{ij} = u + T_i + E_{ij}$, where x_{ij} is the observation of interest in the j^{th} plot of the i^{th} treatment, and T_i is the effect of the treatment mean and with a random error term E_{ij}. The subscript j now represents all of the plots from each subunit in the i^{th} treatment. j = 150 or less.

(a) Assumption: Subsequent yearly samples are independent, taken from the same population.

(b) Hypotheses Tested:

	Treatment		Checks
H1:	year 1 = year 2		year 1 = year 2
H2:	year 2 = year 3		year 2 = year 3
H3:	year 1	=	year 1
H4:	year 2	=	year 2
H5:	year 3	=	year 3

If the treatment effectiveness is long-term, the following results may be expected from testing the various hypothesis:

H3: Expect to be the same
H4, H5: Expect to be different

H1, H2: For the checks, expect to be the same
H1: For treated, expect to be different
H2: For treated, expect to be the same

Since all data can be pooled for the same population and treated as one sample, i.e., 25 clusters for each of six subunits or 150 observations, the test for a difference would be extremely sensitive. However, the intent is not to be able to detect small differences, but rather to be able to state that the residual population in the treated population remains at a low level, i.e., 2-5 budworm per 100 buds.

Further work in time series analysis, i.e., continuous sampling from the same population, will be evaluated to see if other forms of analysis would be more appropriate.

B. Tree Damage Appraisal Phases

1. Evaluating Defoliation

a. Immediate

Defoliation on Douglas-fir was sampled on 15 clusters in each subunit. White fir clusters were selected in eight subunits (subunits 2, 3, 4, and 5 in the treatment area, and 8, 9, 10, and 11 in the untreated areas, Figures 1 and 2). The white fir clusters are adjacent to the Douglas-fir clusters. On all clusters, three codominant Douglas-fir and three codominant white fir trees, 30 to 50 feet tall, with relatively open-grown crowns, were sampled.

Sample branches consisted of four apical branches, 70 cm in length, taken from four quadrants at midcrown of each sample tree. From each of these branch samples, 25 new shoots were examined for current defoliation using the left side of one branch and the right side of another, and so on. Each new shoot was individually examined for defoliation and assigned an index value as follows:

6-class

Defoliation class %	Index value	Midpoint value %
0	0	0
1-25	1	12.5
26-50	2	37.5
51-75	3	62.5
76-99	4	87.5
100	5	100

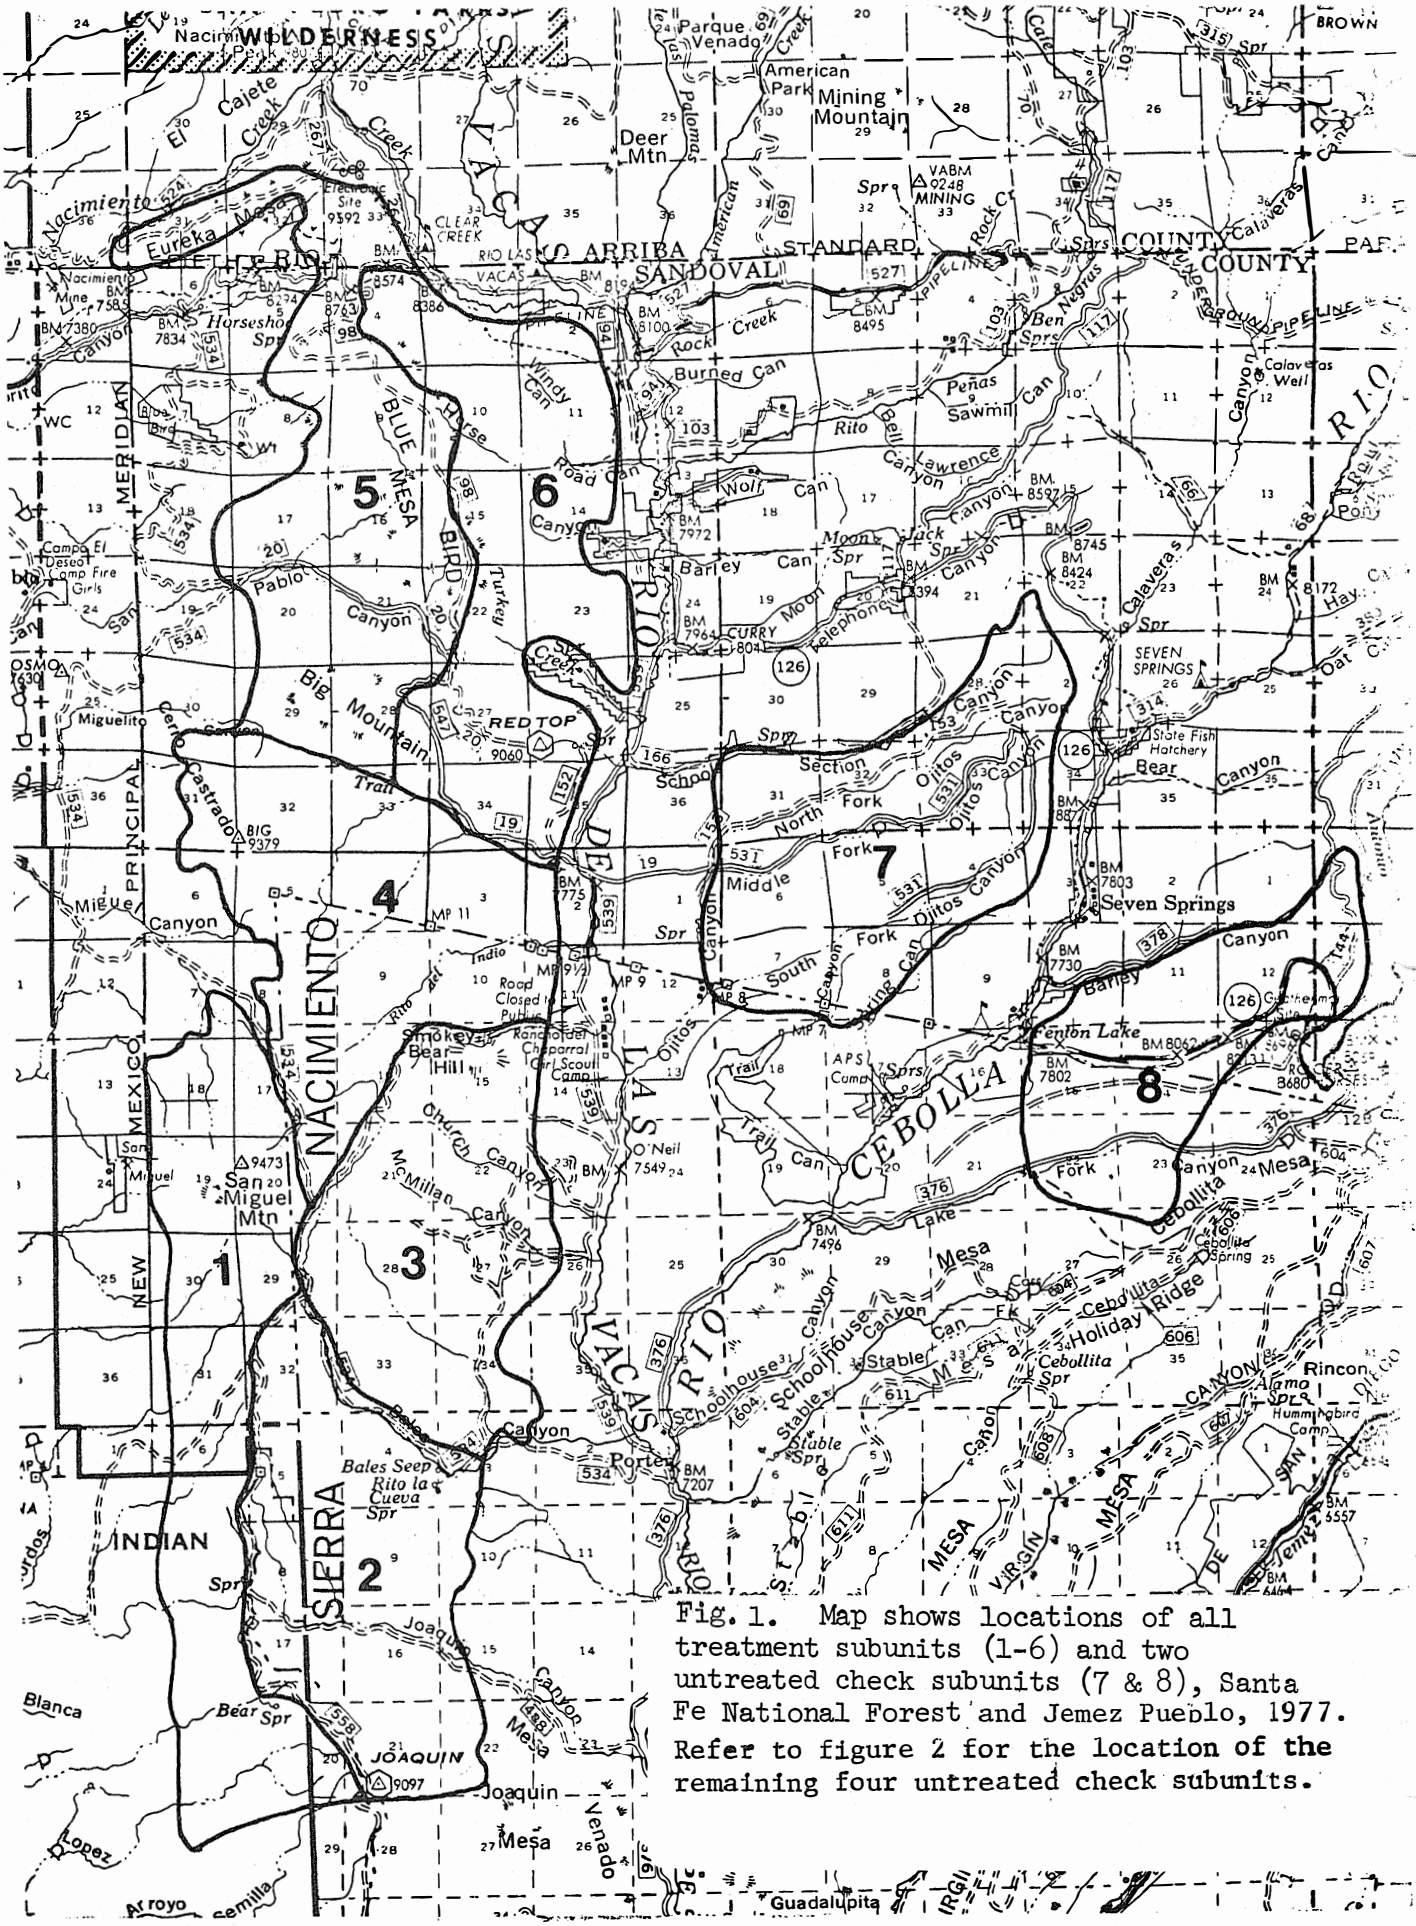

Fig. 1. Map shows locations of all treatment subunits (1-6) and two untreated check subunits (7 & 8), Santa Fe National Forest and Jemez Pueblo, 1977. Refer to figure 2 for the location of the remaining four untreated check subunits.

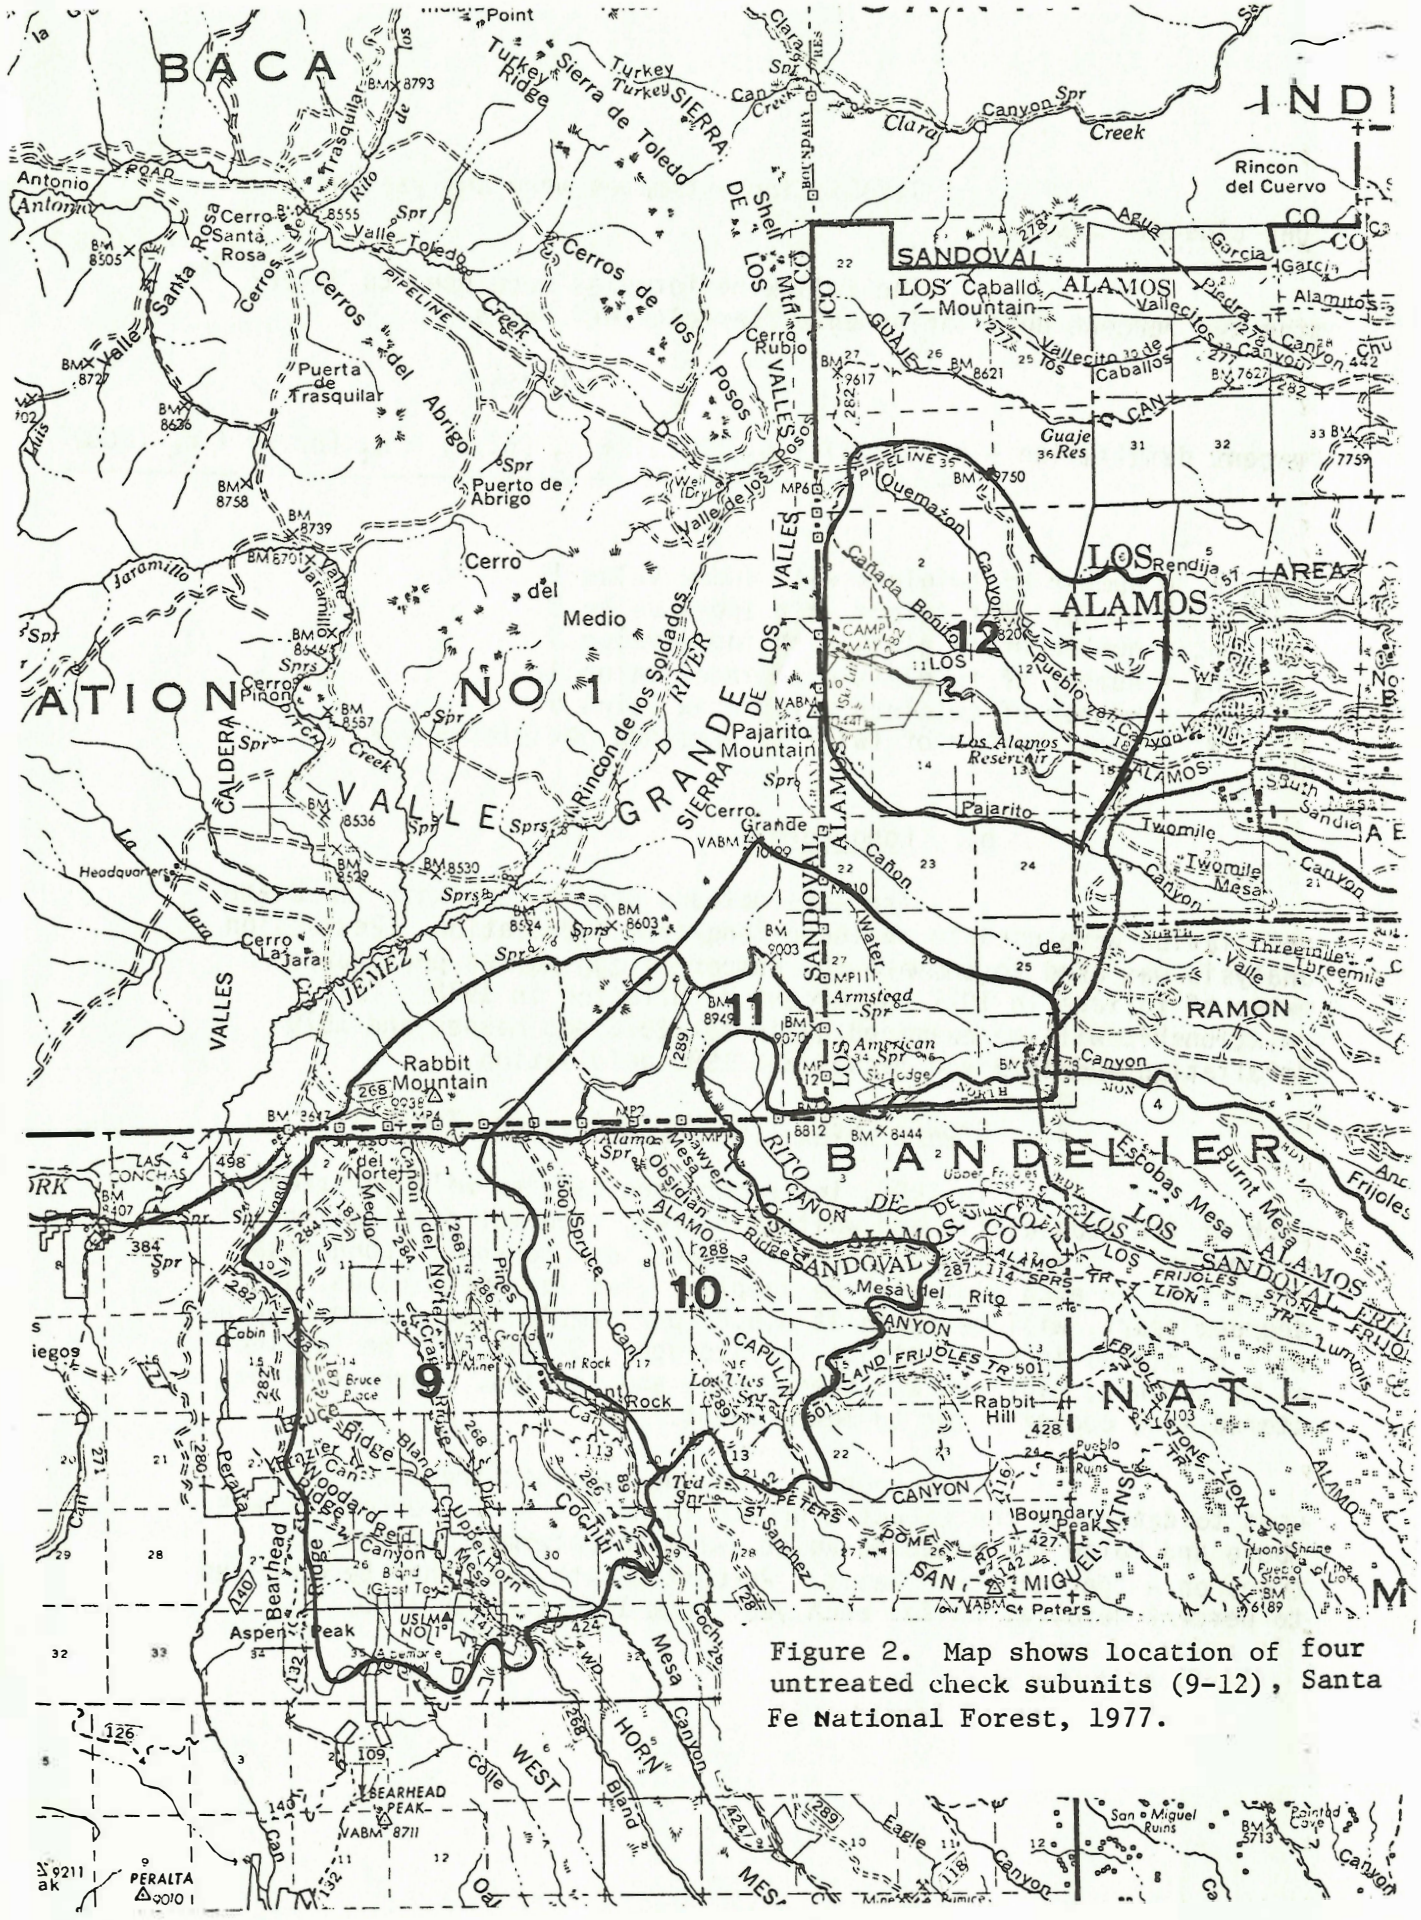

Figure 2. Map shows location of four untreated check subunits (9-12), Santa Fe National Forest, 1977.

Defoliation estimates were analyzed on a "per cluster" basis.

The following formulas were used to determine the percent defoliation on a "per cluster" basis.

6-Class

$$\text{Percent defoliation} = \frac{n_1\ (12.5) + n_2\ (37.5) + n_3\ (62.5) + n_4\ (87.5) + n_5\ (100)}{N}$$

where n_1 = number of twiglets with index value 1
n_2 = number of twiglets with index value 2
n_3 = number of twiglets with index value 3
n_4 = number of twiglets with index value 4
n_5 = number of twiglets with index value 5
N = total number of twiglets examined per plot = 300

b. Long-term

The same methods used to evaluate immediate defoliation were used to evaluate long-term defoliation. Regression analysis was used to compare the number of egg masses per square meter of foliage in 1977 to percent defoliation in 1978. This relationship will be examined again for 1978 egg masses and 1979 defoliation and 1979 egg masses and 1980 defoliation.

2. Growth Loss, Tree Mortality, and Top-kill

In 1980, increment core samples will be taken on each of the Douglas-fir and white fir trees used for defoliation estimates. In addition to the host trees, one non-host (ponderosa pine) tree on each plot will be sampled. Two increment cores, 90 degrees apart, will be taken at d.b.h. per sample tree. Core samples will be placed in paper straws for storage. Straws will be labeled as to subunit, cluster, and tree number and species. Cores will be stored in a cooler prior to measurement.

Core samples from the non-host trees will be used to determine the expected growth in host trees. Percent growth, above and below the expected value, will be determined for host trees on a "per cluster" basis. Percent growth will then be compared to percent defoliation for each year from 1977 through 1980.

Seedling and sapling (0.1 to 4.9 inches d.b.h.) mortality will be evaluated on all 25 clusters in each of the treated and untreated subunits. On each cluster, a permanent 1/100-acre circular subplot was established in 1977. All seedlings and saplings on the subplot were recorded by tree species and damage (live or dead). Trees with a d.b.h. of 0.5 to 4.9 inches are considered as saplings. Trees with a d.b.h. of less than 0.5 inches, or trees less than 4.5 feet in height, were considered as seedlings. Trees killed by the budworm will be recorded in 1979.

Mortality and top-kill of sawtimber-size trees will be evaluated in both the treated and untreated subunits in 1980. In 1977, 12 1-acre plots were photographed at a scale of 1:3300 on a photographic strip in each of the 12 units. A forward overlay of 60 percent was used. The aerial platform consisted of a Cessna 206 aircraft equipped with a 70 mm Hasselblad EL/M camera, a 250 mm lens, and Wratten 12 filter equivalent, using 2443 infrared aerial Kodak film. The film was interpreted with a Bausch and Lomb 240 Z stereoscope, mounted on a light table.

Eleven ground truth plots (five treatment and six untreated subunits) were selected for ground examination. One plot in a treatment subunit was not checked because of adverse weather. This plot was examined in the spring of 1978. A hand-held stereo viewer, with an independent light source, was used to view the photo plots in the field for establishing boundaries. One side of the boundaries of the ground plots was measured using slope correction factors. Plot corners were staked, and string was used to delineate boundaries. All mortality and top-kill within plots were recorded.

Double sampling with regression was used to obtain an estimate of mortality and top-kill in the treatment and untreated units.

The following prediction equation was used to obtain an adjusted estimate of trees per plot (Wear et al. 1966 [3/]):

$$YRd = Y_2 + b\,(x_1 - x_2)$$

where:

YRd = estimate of average number of dead or damaged trees from a regression double sample

3/ Wear, J. F., R. B. Pope, and P. W. Orr. 1966. Aerial photographic techniques for estimating damage by insects in Western forests. USDA. Forest Serv., Pacific Northwest Forest and Range Exp. Sta., Portland, Oregon.

Y_2 = mean of all field plot measurements in the ground truth subsample

b = regression coefficient of field on photo measurements from those plots that have both photo and ground truth data

x_1 = mean photo measurement of numbers of dead or damaged trees from the large sample of photo plots

x_2 = mean photo measurement of number of dead or damaged trees from only those plots with ground truth measurements

The 12, 1-acre plots again will be photographed in 1980, and tree mortality and top-kill data will be recorded.

C. Monitoring

1. Aquatic Organisms

Two small creeks (San Pablo and Trail) were monitored in 1978 to assess the effects of the treatment on aquatic organisms 1 year after spraying. U. S. Fish and Wildlife Service personnel did the sampling, which consisted of obtaining creek drift samples using a 10-inch ring net and Surber square foot bottom samples. Samples were taken at one site on each stream.

2. Birds, Small Mammals, Reptiles, and Non-target Terrestrial Insects

The purpose of the monitoring was to assess the effects of spraying with carbaryl 1 year after treatment. Methods used in 1977 were repeated in 1978. However, no reptiles were found in the 1977 sampling, and they were not monitored in 1978. Also, studies on non-target insect populations in 1977 yield such variable data that comparisons could not be made this year, and no samples were taken in 1978.

a. Birds

For avian populations, the same study site used in 1977, 1-mile segment on Smokey Bear Hill Road (subunit 3), was sampled in 1978. One observer censused breeding birds on the 1-mile transect using a modified Emlen Transect Method (Emlen 1971).[4/] Censuses were done on June 27, 28, and 29, 1978.

4/ Emlen, J. T. 1971. Population densities of birds derived from transect counts. Auk 88:323-342.

b. Small Mammals

Small mammal trap lines were set in June and July 1978 to determine if there were effects on population density due to treatment. Trap lines were set at the same two sites censused in 1977: treatment area, Bales Canyon on Smokey Bear Hill Road, elevation 2,700 m; and untreated check area, Lake Fork Canyon at 7.2 km northeast of Parter's Landing, 2,500 m in elevation. Trap lines consisted of 100 Museum Special snap traps baited with oatmeal. The lines were run for 3 nights and 2 days at each site; June 26, 27, and 28 in Bales Canyon and July 3, 4, and 5 in Lake Fork Canyon.

3. Insect Parasites of the Western Spruce Budworm

John Schmid, Rocky Mountain Forest and Range Experiment Station, Ft. Collins, Colorado, completed the second year's sampling to determine the incidence of insect parasitism. Budworm larvae and pupae were collected from at least 20 trees in each of six treated and six untreated check subunits. Larval and pupal parasites were then reared and identified to determine parasitism, and which parasites were present.

III. RESULTS

A. Entomological Phases

1. Larval Density

Suppression effects were achieved in the treatment area for a second year. An average of 14.9 larvae per 100 buds was found on Douglas-fir in the 1977 pre-spray sample, about one larva per 100 buds remaining 14 days following treatment, and less than 1 larva per 100 buds was present when the 1978 pre-spray sample was taken. Refer to Table 1 for average larval densities in subunits 1-6. In the untreated check area, average pre-spray densities per 100 buds follow: 1977, 12.4; 1978, 8.7. Again, refer to Table 1 for average larval densities in untreated check subunits 7-12. There was a natural decline in the infestation intensity in the untreated area from 1977 to 1978. The factor that caused this decline may have helped to keep the suppressed budworm population at a low level. However, there was still a significant difference between the larval densities in the treatment and check subunits (Fig. 3).

2. Egg Mass Densities

Egg mass density data for all subunits are shown in Table 2. The treatment area had an average of 1.7 new egg masses per meter square of foliage following treatment in 1977. The 1978 density dropped to 0.4 egg masses per meter square of foliage. In the untreated subunits, the average 1977 egg mass density was 5.8

Table 1.--Western spruce budworm larvae per 100 buds on Douglas-fir for 1977 pre- and post-spray samples and 1978 pre-spray samples, Santa Fe National Forest and Jemez Pueblo lands, New Mexico.

Subunit	No. of Plots	Budworm Larvae Per 100 Buds

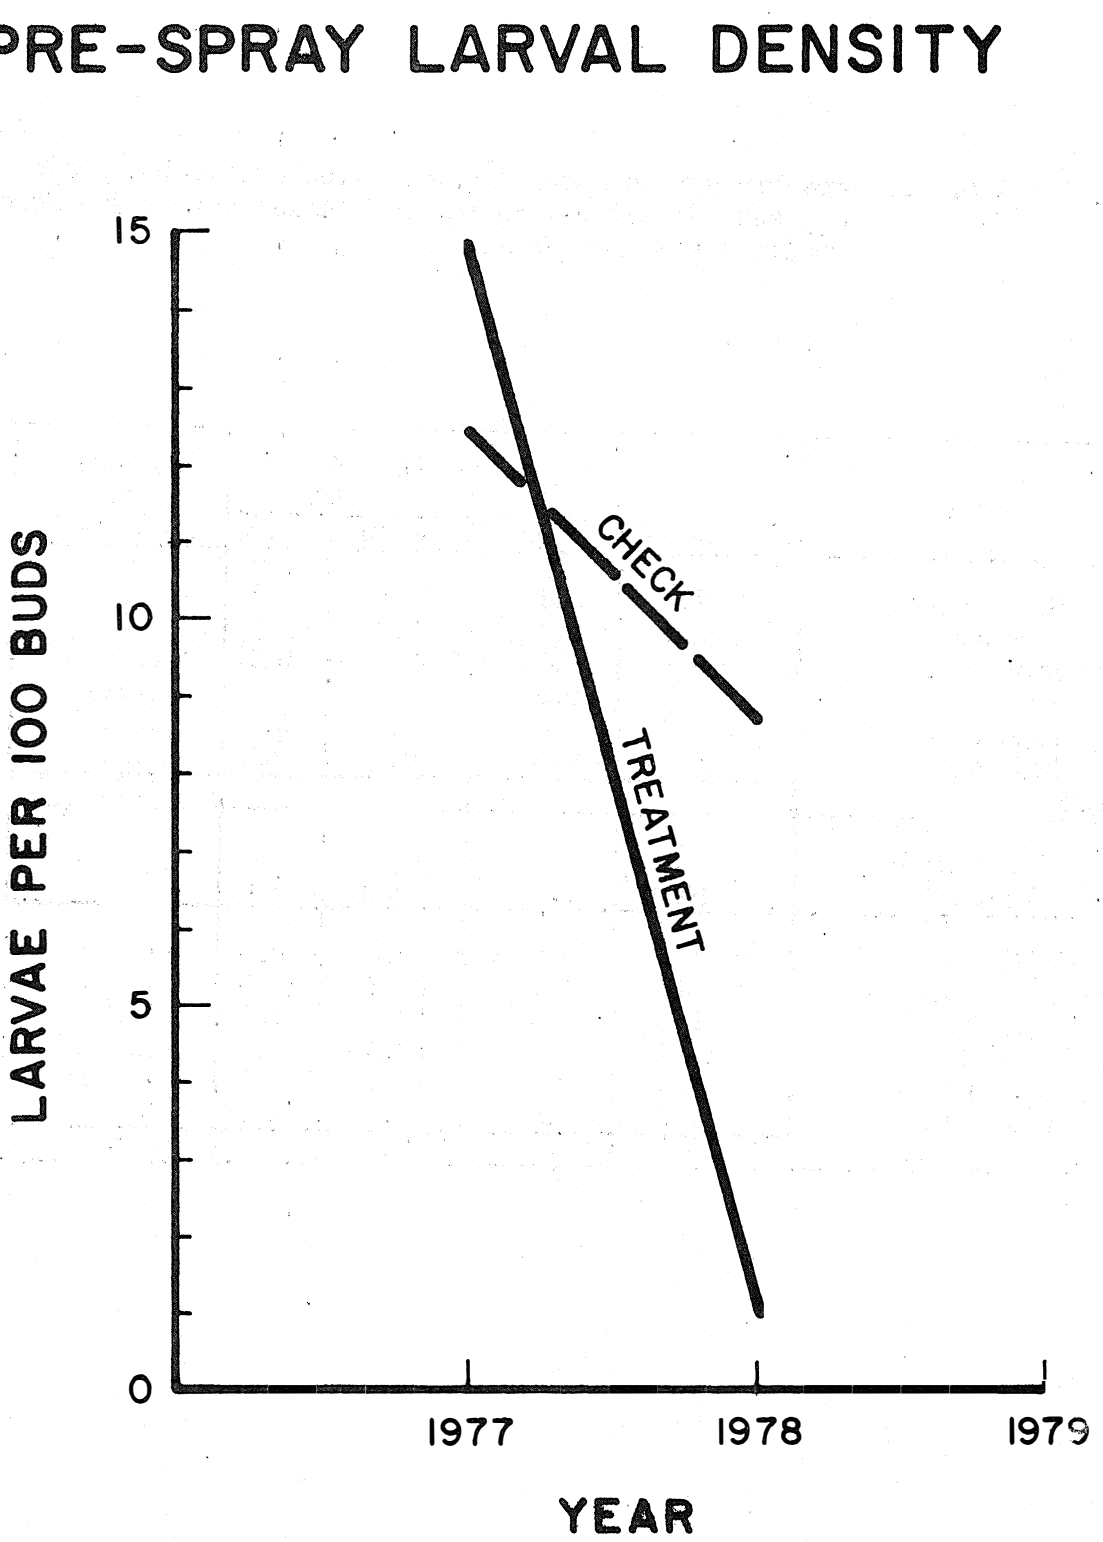

Figure 3.--This graph compares average larval densities by year in the treatment and untreated check areas. Sampling was initiated when 20 percent of the larvae were in the fifth and sixth instars and completed before 5 percent of the larvae had pupated, Santa Fe National Forest and Jemez Pueblo Lands, New Mexico.

Table 2.--Western spruce budworm suppression-evaluation project egg mass densities, Santa Fe National Forest and Jemez Pueblo lands, New Mexico.

Treated Subunits	Egg Masses Per m^2 1977 Mean	1977 S.E.	1978 Mean	1978 S.E.	Egg Mass Ratio 1978:1977	1979 Infestation trend
1 San Miguel	4.2	1.1	0.9	0.3	0.2:1	decreasing
2 Joaquin	1.4	0.5	0.0	0.0	-0-	---
3 Smokey Bear	0.2	0.1	0.2	0.1	1.0:1	static
4 Trail	1.9	0.6	0.6	0.2	0.3:1	decreasing
5 Blue Bird	1.2	0.4	0.4	0.2	0.3:1	decreasing
6 Red Top	1.0	0.3	0.5	0.2	0.5:1	decreasing
Average	1.7		0.4		0.2:1	decreasing
Untreated Subunits	Mean	S.E.	Mean	S.E.		
7 Ojitos	1.0	0.3	1.0	0.3	1.0:1	static
8 Lake Fork	7.5	1.7	11.2	2.6	1.5:1	increasing
9 Cochiti	11.6	2.9	12.4	2.5	1.1:1	increasing
10 Capulin	14.4	2.5	12.5	1.9	0.9:1	decreasing
11 Am. Springs	7.4	1.1	11.1	1.7	1.5:1	increasing
12 Los Alamos	17.5	2.6	12.5	1.9	0.7:1	decreasing
Average	9.9		10.1		1.0:1	static

times greater (9.9 egg mass per meter square of foliage) than in the treatment area. In 1978, there was an average of 10.1 egg masses per meter square in the untreated subunits, which is 25 times greater than in treatment subunits (Fig. 4).

A comparison of 1977 to 1978 egg mass densities shows that there will be a general decrease in the infestation trend in treatment subunits. For untreated subunits, the following trends will occur: increasing, subunits 8, 9, and 11; static, subunit 7; and decreasing, 10 and 12.

Overall, egg mass density data indicate that larval densities will remain at about the same level in untreated check subunits, but decrease in treatment subunits. Therefore, suppression success should be achieved for a third year.

B. Tree Damage Appraisal Phase

1. Defoliation

There was a significant reduction in defoliation in the treatment area compared with the untreated check area for both 1977 and 1978 (Table 3). In 1977, treatment was conducted after 20 percent of the budworm larvae were in the fifth and sixth instars, which would lead one to believe that treatment would not reduce defoliation. However, defoliation was lower in the treatment area, which had comparable larval densities with subunits 8-12. The average savings in foliage was about 40 percent for white fir and 35 percent for Douglas-fir. These percentages, which are rough estimates, were calculated as follows: 61.3 (defoliation in the check area) minus 37.0 (defoliation that occurred in the treatment area before treatment) divided by 61.3. As would be expected, the amount of foliage savings in 1978 was even greater: white fir, 89 percent; Douglas-fir, 90 percent.

Refer to Figure 5 for a comparison of defoliation data in the treatment and untreated check areas.

2. Other Tree Damages

Information on growth loss, top-killing, and tree mortality will be collected in 1980. Results will be presented in future reports.

EGG MASS DENSITY

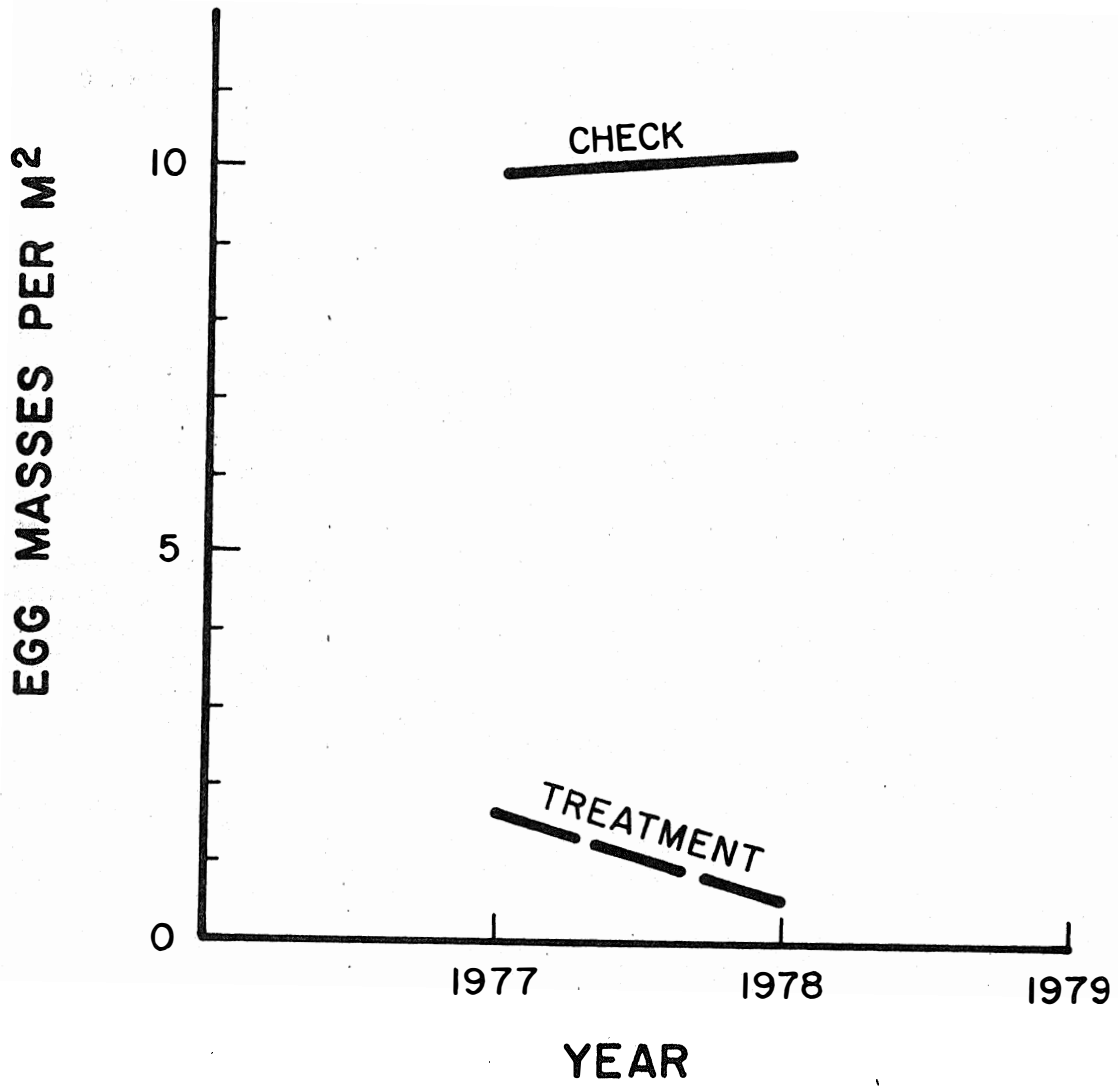

Figure 4.--This graph compares average egg mass densities by year in the treatment and untreated check areas. Besides the significantly lower density of egg masses in the treatment area, these data show that suppression will be achieved for a third year, Santa Fe National Forest and Jemez Pueblo lands, New Mexico.

Table 3.--Percent defoliation by subunit for white fir and Douglas-fir, 6-class system, Santa Fe National Forest and Jemez Pueblo lands, New Mexico.

Treated Subunits	% def.-white fir 1977	% def.-white fir 1978	% def.-Douglas-fir 1977	% def.-Douglas-fir 1978
1 San Miguel			41.6	4.5
2 Joaquin	28.6	3.1	19.9	1.5
3 Smokey Bear	24.8	5.2	18.0	1.1

5 Blue Bird	41.8	5.7	25.8	2.7
6 Red Top			16.6	2.0
Average	37.0	5.3	26.5	2.9
Untreated Subunits				
7 Ojitos			14.1	9.4
8 Lake Fork	62.2	58.1	51.1	40.9
9 Cochiti	52.8	46.8	37.2	35.3
10 Capulin	63.6	38.7	51.2	29.0
11 Am. Springs	66.4	46.3	34.2	29.1
12 Los Alamos			56.7	23.8
Average	61.3	47.5	40.8	27.9

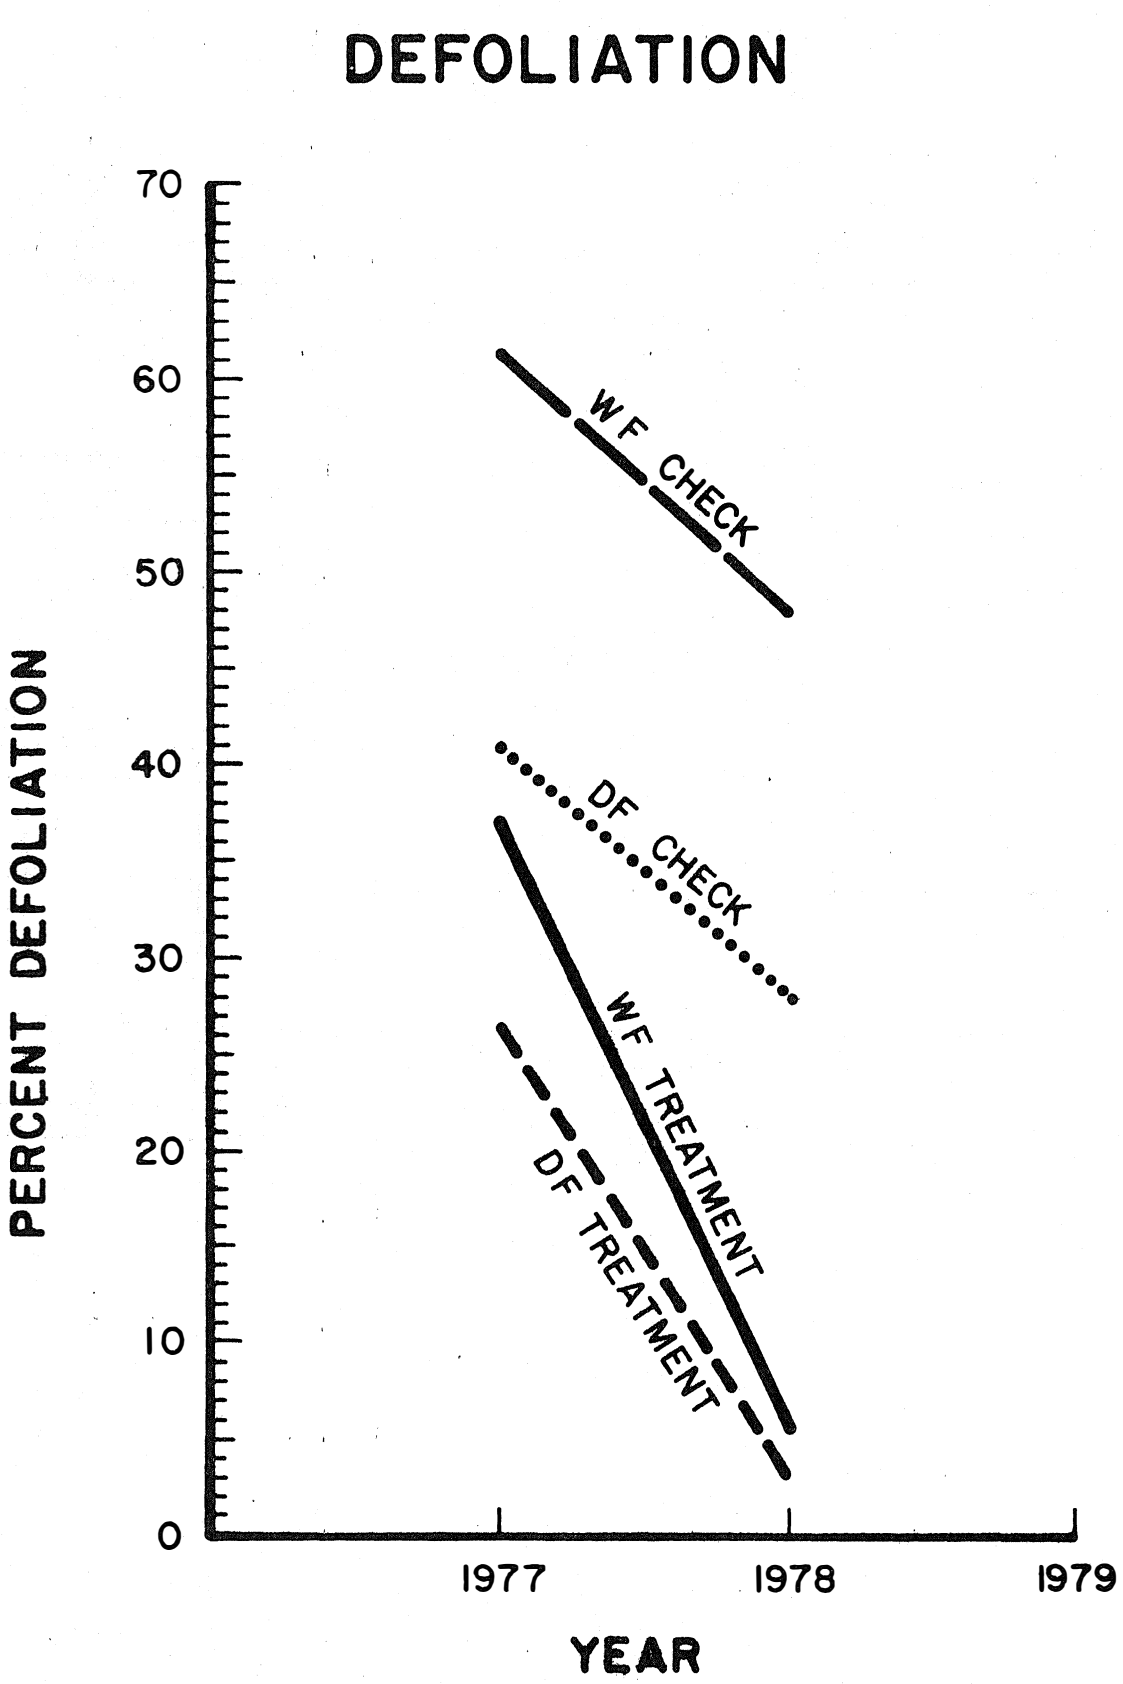

Figure 5.--This graph compares average defoliation of Douglas-fir (DF) and white fir (WF) by year in the treatment and untreated check areas. Defoliation in the treatment area was considerably lower for both tree species in the treatment year (1977) and the following year, Santa Fe National Forest and Jemez Pueblo lands, New Mexico.

C. Monitoring

1. Aquatic Organisms [5/]

Of the three creeks monitored in 1977, San Pablo Creek was the only stream where the effects of treatment on aquatic insects were demonstrated. This occurred primarily because a portion of the creek was oversprayed. The creek itself is about 2 feet wide, a few inches deep, about 4 miles long, and covered by brush and trees. The other two creeks, Rito la Cueva and Trail, were not adversely affected by the carbaryl application, although some carbaryl drift occurred in the upper reaches of Trail Creek, causing a minor die-off of aquatic insects. Data will not be presented for these two creeks.

In 1977, the aquatic invertebrate fauna of San Pablo Creek was reduced by the carbaryl overspray. Because of this impact on the aquatic environment, a follow-up investigation was made in June of 1978, 1 year after the overspray. Sampling was done to determine if the most seriously affected groups of aquatic insects would be present. For comparison purposes, Table 4 shows the effects of the carbaryl overspray of San Pablo Creek on Treatment Day in 1977 for both drift and Surber samples. Data obtained for drift and Surber samples are also presented for each study period. These data indicate what occurred at one site on the stream where samples were taken.

The impact of the carbaryl overspray is quite obvious for those samples obtained on Treatment Day. The number of drift organisms noted represents the total number of organisms collected from two 10-minute drift samples taken at 7:30 and 8:00 a.m. MDT, the peak of the drift increase. Part of the creek was oversprayed between 6:00 and 6:30 a.m. MDT. Analyses of these drift samples indicated that the most severely affected insects were mayflies of the families Baetidae and Heptageniidae, Plecoptera nymphs of the families Chloroperlidae and Nemouridae, Trichoptera larvae of the families Lepidostomatidae and Limnephilidae, and Diptera larvae of the family Tipulidae.

On Treatment Day, one Surber sample was taken from San Pablo Creek at 1:00 p.m. MDT. The analysis of this sample indicated a total of 215 organisms representing all groups of insects that were also present in the Pretreatment sample. This was possibly not a representative sample, however, as the high number of organisms collected may have been the result of placing the sampler over an area that contained insects that died earlier in the day and had settled to the bottom.

5/ Report prepared by Harry Kennedy, U. S. Fish and Wildlife Service, Albuquerque, NM.

1/ Total number of organisms from two 10 minute drift samples taken at 7:30 a.m. and 8:00 a.m. MDT.
2/ Total number of organisms from two 10 minute drift samples taken at 7:30 and 8:00 a.m. MDT.
3/ Total number of organisms collected from one Surber sample taken at 1:00 p.m. MDT for each sampling period.

From the analyses of drift and Surber samples obtained in June of 1978, there is an indication that three families of aquatic insects may not have recovered, namely Chloroperlidae and Nemouridae of the order Plecoptera, and Stratiomyidae of the order Diptera. It appears that the other groups of insects, though affected by the carbaryl, had reestablished themselves to their normal population density. Overall, the insect biomass appears to be comparable for both years. The number of Planaria, Tubellaria, increased from 1977 to 1978. Planaria were also more numerous in Surber samples for the 2 years; 10 from the Pretreatment sample in June of 1977 to 64 in June of 1978.

Additional samples will be taken at several sites on San Pablo Creek in 1979 to determine if the families of aquatic insects that did not appear in the 1978 samples were completely eliminated, or only temporarily affected. Because of various physical limitations (sample size, climatic conditions, or sampling techniques), it is not possible to definitely say that these affected groups of insects no longer form a part of the insect fauna of San Pablo Creek.

2. Birds, Small Mammals, Reptiles, and Non-target Terrestrial Insects

a. Birds

In total, 25 species of breeding birds were observed in 1978, compared with 40 species observed in 1977. The 15 species not encountered in 1978 are all uncommon; thus, our census data may simply reflect the shorter period of time spent in the field in 1978. The total breeding bird density was 161.7 pairs/40 ha, not significantly different from the densities encountered in 1977.

When the transect was censused in 1977, the weather was clear, while we encountered rain on all but one census period in 1978. Birds are often less active under rainy or cloudy conditions; thus, the adverse weather may have influenced our data.

While the total number of pairs/ha was near the 1977 levels, some species densities changed considerably (Table 5). There are insufficient data to determine whether these changes were a result of the carbaryl treatment or natural population fluctuations.[6/]

Data from 1977 and 1978 breeding bird surveys in the Jemez Mountains did not indicate significant changes in the avian population that could be directly linked to the carbaryl

* Not observed in 1978.

treatment. It is important to note, however, that the study design was not sensitive enough to measure other than large changes in the breeding bird densities, i.e., massive reductions in numbers of adult and juvenile birds and complete failure of nests.

b. Small Mammals

The results of the small mammal trapping in June-July 1978 are given in Tables 6 and 7, along with the June 1977 results for comparison. The method detected no immediate effects of the spray treatment in 1977. In the 1978 sampling, the size as well as the diversity of the overall catch increased at both the sprayed and unsprayed sites. There is no evidence in these data that would indicate that the carbaryl spraying had an adverse effect on small mammal populations.

3. Insect Parasites of the Western Spruce Budworm

Parasitism rates for 1977 and 1978 are presented in Tables 8 and 9. Only Apanteles fumiferanae Viereck, Glypta fumiferanae (Viereck), and Ceromasia auricaudata Townsend were abundant enough for yearly comparison. Other species were relatively rare and not comparable. A. fumiferanae parasitism on early budworm instars increased or remained static from 1977 to 1978 in the sprayed subunits, while it substantially decreased in unsprayed subunits (Table 8). G. fumiferanae, on the other hand, shows a decrease in most sprayed subunits, while the change in percent parasitism is mixed in unsprayed subunits. Comparing the percent parasitism in Table 9, it is evident that a similar trend occurs for both parasite species on budworm larvae in latter instars. These data have not been analyzed statistically as yet, but it appears that the percent parasitism for A. fumiferanae was not detrimentally affected, and may have increased due to the treatment program. Spraying may have reduced G. fumiferanae parasitism. The most significant reduction in percent parasitism is evident for C. auricaudata (Table 9) in the treatment area.

IV. PLAN FOR F.Y. 1979

Evaluation of the effectiveness of suppression 2 years following treatment is planned for F.Y. 1979. Entomological and tree damage sampling methods will be the same as those described in Sections II. A. and B. Total costs are expected to be $69,157: $49,000 project funding and $19,957 base funding. A F.Y. 1979 financial plan follows:

Table 6. Results of small mammal trapping in the sprayed area during 1978 compared with the 1977 trapping, Smokey Bear Hill Road, Bales Canyon, Santa Fe National Forest, New Mexico.

Environmental monitoring will be continued in 1979 for aquatic organisms and insect parasites of the budworm. Sampling of aquatic organisms in San Pablo Creek will be done to determine if insect species, reduced by the accidental overspraying, have returned. The work to determine the percent parasitism in treatment and untreated check areas will be done for a third year.

Finally, plans are being made to continue evaluating the long-term effects of suppression in 1980, and in future years, until the budworm outbreak collapses, if funding can be obtained. Sampling probably will not be as intensive as planned for the first 3 years of the project, unless it is determined that detailed data are needed for studies for CANUSA 7/ or other programs. In this case, CANUSA personnel and/or other cooperators would participate with Regional personnel.

7/ CANUSA, Canada/U.S. Spruce Budworms Program--West, Pacific Northwest Forest and Range Exp. Sta., P.O. Box 3141, Portland, Oregon 97208.

V. APPENDIX

An explanation of information presented on data summary sheets follows:

A. Cluster numbering system: cluster 1 = trees 1, 2, and 3; cluster 4 = trees 4, 5, and 6; etc.

B. Larval densities per 100 buds is on Douglas-fir.

C. Host codes: 1 = Douglas-fir, 3 = white fir.

D. Egg mass data: Good, less than 50 percent of eggs parasitized; bad, more than 50 percent of eggs parasitized.

E. Refer to Progress Report No. 1 (footnote 1) for an explanation of the 4-class defoliation system.

A. Unanalyzed Larval Density Data - 1977 & 1978
